EXPERIMENTS ON THE SYNTHESIS OF ELEMENT 115 IN THE REACTION ²⁴³Am (⁴⁸Ca, *xn*)^{291-x}115

Submitted to «Physical Review C»

^{*}University of California, Lawrence Livermore National Laboratory, Livermore, California 94551, USA

I. INTRODUCTION

Our previous experiments were designed to synthesize even-Z superheavy elements (114-118) in the ⁴⁸Ca-induced reactions with actinide targets ²⁴⁴Pu [1], ²⁴⁸Cm [2] and ²⁴⁹Cf [3]. The observed fusion-evaporation reaction products underwent two or three consecutive α -decays terminated by spontaneous fission (SF).

For the neighboring odd-Z elements, especially their odd-odd isotopes, the probability of α -decay with respect to SF should increase due to hindrance for SF. For such odd-Z nuclei one might expect longer consecutive α -decay chains terminated by the SF of relatively light descendant nuclides (Z \leq 105).

The decay pattern of these superheavy nuclei is of interest for nuclear theory. In the course of α -decays, the increased stability of nuclei caused by the predicted spherical neutron shell N=184 (or perhaps N=172) should gradually become weaker for descendant isotopes. However, the stability of these nuclei at the end of the decay chains should increase again due to the influence of the deformed shell at N=162.

The observation of nuclei passing from spherical to deformed shapes in the course of their consecutive α -decays could provide valuable information about the influence of significant nuclear structure changes on the decay properties of these nuclei. For these investigations, we chose the fusion-evaporation reaction ²⁴³Am+⁴⁸Ca, leading to isotopes of element 115. According to calculations based on the results of experiments on the synthesis of even-*Z* nuclei [1-4], the 3*n*- and 4*n*-evaporation channels leading to isotopes ²⁸⁸115 (*N*=173) and ²⁸⁷115 (*N*=172) should be observed with the highest yields.

II. EXPERIMENT

The experiments were performed between July 14 and August 10, 2003, at the U400 cyclotron with the Dubna gas-filled recoil separator (DGFRS). The average incident beam intensity was 1.3 pµA. Over this period, equal beam doses of 4.3×10^{18} ⁴⁸Ca projectiles were delivered to the target at two bombarding energies. In this experiment, we chose the laboratory energies for the ⁴⁸Ca ions of 248 MeV and 253 MeV in the middle of the target. The systematic uncertainty in the beam energy is ~1 MeV. With the beam energy resolution, small variation of the beam energy during irradiation, and energy losses in the target (~3.3 MeV), we expected the resulting compound nuclei ²⁹¹115 to have excitation energies between 38.0-42.3 MeV and 42.4-46.5 MeV, respectively [5].

The 32-cm² rotating target consisted of the enriched isotope ²⁴³Am (99.9%) in the form of AmO₂. The target material was deposited onto 1.5- μ m Ti foils to a thickness corresponding to ~0.36 mg cm⁻² of ²⁴³Am.

The evaporation residues (EVRs) recoiling from the target were separated in flight from the ⁴⁸Ca beam ions, scattered particles and transfer-reaction products by the DGFRS [6]. The transmission efficiency of the separator for Z=115 nuclei was estimated to be about 35% [6].

The detection system consisted of a multiwire proportional counter to measure timeof-flight (TOF) and a 4×12 -cm² semiconductor focal-plane detector array with 12 vertical position-sensitive strips to measure the decay of the implanted recoils. This detector, in turn, was surrounded by eight 4×4-cm² side detectors without position sensitivity, forming a box of detectors open from the front side. The detection efficiency for α -decays of implanted nuclei was 87% of 4 π . The detection system was tested by registering the recoil nuclei and α - and SF-decays of the known isotopes of No and Th, as well as their descendants, produced in the reactions ²⁰⁶Pb(⁴⁸Ca, 2*n*) and ^{nat}Yb(⁴⁸Ca, 3-5*n*). The energy resolution for α -particles absorbed in the focal-plane detector was 60-100 keV, depending on the strip and the position in the strip. For α 's escaping the focalplane detector at different angles and registered by side detectors, the energy resolution of the summed signals was 140-200 keV. The FWHM position resolutions of correlated decays of nuclei implanted in the focal-plane detector were 0.9-1.9 mm for EVR- α correlations and 0.5-0.9 mm for EVR-SF correlations. If both the focal-plane and a side detector detected an α -particle, the position resolution depended on the amplitude of the signal in the focal-plane detector (see, e.g., Fig. 4 in [3]), but was generally inferior to that obtained for the full-energy signal.

Fission fragments from ²⁵²No implants produced in the ²⁰⁶Pb+⁴⁸Ca reaction were used for a fission-energy calibration. The measured fragment energies were not corrected for the pulse-height defect of the detectors, or for the energy loss in the detectors' entrance windows, dead layers, and low-pressure pentane gas filling the detection system. The mean sum energy loss of fission fragments from the SF-decay of ²⁵²No was estimated to be about 20 MeV.

To greatly reduce the background, we switched off the beam after a recoil signal was detected with preset parameters of implantation energy and TOF expected for Z=115 evaporation residues, followed by an α -like signal with an energy of 9.6 MeV $\leq E_{\alpha} \leq 11.0$ MeV in the same strip, within a position window of 1.4-1.9 mm and time interval of up to 8 s. The beam-off interval was initially set at 2 minutes. If, in this time interval, an α -particle with $E_{\alpha}>8.6$ MeV was registered, the beam-off interval was extended to between 12 minutes and 2.5 hours. Thus, all the expected sequential decays of the daughter nuclides with $Z\leq 113$ could be observed under very low background conditions.

III. EXPERIMENTAL RESULTS AND DISCUSSION

The three similar decay chains observed at 248 MeV are shown in Fig. 1a. The implantations of recoils in strips 2, 3 and 4 of the focal-plane detector were followed by α -particles with E_{α} =10.46±0.06 MeV. These sequences switched the ion beam off, and four more α -decays were detected in time intervals of 29 s, 15 s, and 20 s, respectively, in the absence of a beam-associated background. The last α -decay in the first chain and second and fourth α -decays in the second chain were registered by the side detectors only. The energies deposited by these α -particles in the focal-plane detector were not registered. However, with the actual α -counting rates, the probability that these α -particles appeared in the detector (Δt ~30 s) as random events can be estimated to be approximately 1.5% [7], so we assign them to the decay of the same implanted nuclei. During the remainder of the 2.5 h beam-off period following the last position-correlated α -particle, no α -particles with E_{α} >7.6 MeV were registered by the focal-plane

detectors. The SF-decay of the final nuclei in these chains was detected 28.7 h, 23.5 h and 16.8 h, respectively, after the last α -decay. A search was performed to identify α -decays correlated closely in time (<60 s) and position to each of the three SF-events in Fig. 1a. No correlations were found.

In the first two decay chains, the focal-plane and side detectors simultaneously detected fission fragments with sum energies of 205 MeV and 200 MeV. In the third chain, only the focal-plane detector registered a fission fragment. All three SF-events were registered in the corresponding strips and positions where the three EVR- α_1 -...- α_5 decay chains were observed (see Fig. 1a). Thus, these SF-events should be assigned to the spontaneous fission of the descendant nuclei in these observed chains.

In the course of this experiment at 248 MeV, we observed only seven spontaneousfission events. In addition to the three previously mentioned events, three other SFevents, with measured energies of 147 MeV, 168 MeV, and 154 MeV, were detected 0.51 ms, 4.1 ms and 2.07 ms after the implantation of corresponding recoil nuclei in strips 12, 10 and 11, respectively. For the second and third event, both the focal-plane and side detectors registered fission fragments. Based on the apparent lifetime, we assign these events to the spontaneous fission of the 0.9-ms ^{244mf}Am isomer, a product of transfer reactions with the ²⁴³Am target. The DGFRS suppresses the yield of such products by a factor of 10⁵. An additional long-lived SF event with E_{sum} =146 MeV was observed in strip 2. This SF event corresponds to the background level of long-lived SF Cf isotopes produced in incomplete fusion reactions in a previous experiment with a ²⁴⁹Cf target [3] where the same set of detectors was used.

At 253 MeV, the aforementioned EVR- α_1 -...- α_5 -SF decay chains were not observed. However, a different decay chain, consisting of four α -decays and a spontaneous fission, was registered (see Fig. 1b). The beam was switched off after the detection of an EVR signal followed in 46.6 ms by an α -particle with E_{α} =10.50 MeV in the same position in strip 7. Three other α decays were detected in a time interval of about 0.4 s in the absence of beam-associated background. After 106 minutes, the terminal SFevent was detected in-beam with a sum energy of 206 MeV in the same position in strip 7 (see Fig. 1b). In addition to this SF event with E_{sum} =206 MeV, the decays of three other long-lived background SF nuclei, with measured fission-fragment energies of 168 MeV, 154 MeV, and 151 MeV, were also observed in strips 4, 3 and 1, respectively.

The radioactive properties of nuclei in this decay chain differ from those of the nuclei observed at the lower bombarding energy. The total decay time of this chain is about 10 times shorter and the α -decays are distinguished by higher α -particle energies and shorter lifetimes. Its production also required increasing the beam energy by about 5 MeV, so this decay chain must originate from another parent nucleus.

It is most reasonable that the different decay chains originate from neighboring parent isotopes of element 115, produced in the complete fusion reaction 243 Am+ 48 Ca followed by evaporation of three and four neutrons from the compound nucleus 291 115. Indeed, at the excitation energy E^* =40 MeV, close to the expected maximum for the 3*n*-evaporation channel, we observed longer decay chains of the odd-odd isotope 288 115.

Fig. 1 Time sequences in the decay chains observed at two ⁴⁸Ca energies E_L =248 MeV (a) and E_L =253 MeV (b). Measured energies, time intervals and positions of the observed decay events are shown. 1) Energies of events detected by both the focal-plane and side detectors. 2) Energies of events detected by side detectors only. We have inserted an unobserved nuclide in the fourth decay chain.

Increasing the beam energy by 5 MeV results in reducing the ²⁸⁸115-isotope yield and, at the same time, increasing the yield of the 4*n*-evaporation channel leading to the evenodd isotope ²⁸⁷115. Corresponding cross sections for the 3*n*- and 4*n*-evaporation channels at the two projectile energies were measured to be $\sigma_{3n}=2.7^{+4.8}_{-1.6}$ pb and $\sigma_{4n}=0.9^{+3.2}_{-0.8}$ pb. Note that these values are in agreement with results of recent experiments [4] where excitation functions for the reaction ²⁴⁴Pu(⁴⁸Ca,*xn*) have been measured.

The decay properties of the product nuclei are presented in Table 1. In the decay chains shown in Fig. 1a, we assigned SF-events to the isotope ²⁶⁸Db following five consecutive α -decays. It is also possible that this isotope undergoes α -decay or electron capture (EC). In the case of the α -decay of ²⁶⁸Db with $T_{\alpha}>2.5$ h (after the beam-off period), one would more reasonably expect SF or EC of ²⁶⁴Lr, because the α -decay of ²⁶⁴Lr seems improbable due to the low expected α -decay energy ($Q_{\alpha}=6.84$ MeV [8], $T_{\alpha}>100$ d). The electron capture of ²⁶⁸Db or ²⁶⁴Lr leads to the even-even isotopes ²⁶⁸Rf or ²⁶⁴No, for which rapid spontaneous fission can be expected (e.g., $T_{SF}=1.4$ s is predicted for ²⁶⁸Rf [9]). Since both fission fragments of these terminal nuclei can have the Z=50 and N=82 closed shell configurations, one would expect their SF-decays to result in narrowly symmetric mass distributions with rather high total kinetic energies, TKE≈230-240 MeV (see, e.g., Ref. [10]). Indeed, the sum fission fragment energies observed for the terminal nuclei are close to this value. Note, the likelihood that EC-decay occurs earlier in the observed decay chains is small because of the short T_{α} for the observed α -decays of elements 115, 113, 111, Mt, and Bh. In the single decay chain originating from ²⁸⁷115 (see Fig. 1b. and Table 1), we

propose that we have missed the α -decay of ²⁷¹Bh. This assumption follows from the α decay properties of nuclei located around N=162 as predicted by macroscopicmicroscopic theory [8]. The expected T_{α} value for ²⁷¹Bh should be ~10 s (Q_{α} =9.07 MeV [8], T_{α} \$\approx 5 s for an allowed transition), which is much shorter than the interval between the last observed α -particle and the terminating SF-event, but is much longer than the intervals between the observed correlated α -particles. A search was performed to identify α -particles with $E_{\alpha} > 7.0$ MeV correlated in position to the observed α -decays. No correlated α -particles were observed within an hour after the last α -decay. In these experiments, we registered 19 α -particles using a detector with 87% efficiency, so the loss of one α -particle seems rather probable. The experimental decay scheme for ²⁸⁷115 is also supported by the agreement of the observed decay properties of the other nuclides in the decay chain with the expectations of theory (see Fig. 2). This means that the SF occurs directly in the decay of ²⁶⁷Db since the calculated α -decay and EC-energies for this isotope are rather low (Q_{α} =7.41 MeV [8], $Q_{\rm EC}$ =1 MeV [5]) and their expected partial half-lives significantly exceed the observed time interval of 106 min.

Isotope	Decay mode	Half-life	E_{α} (MeV)	Q_{α} (MeV)	Isotope	Decay mode	Half-life	E_{α} (MeV)	Q_{α} (MeV)
²⁸⁸ 115	α	87^{+105}_{-30} ms	10.46±0.06	10.61±0.06	²⁸⁷ 115	α	32^{+155}_{-14} ms	10.59±0.09	10.74±0.09

Table 1. Decay properties of nuclei.

Fig. 2 α -decay energy *vs.* neutron number for isotopes of odd-*Z* elements (solid circles – odd-odd isotopes, open circles – even-odd isotopes) [11-15]. Solid lines show theoretical Q_{α} values [8]. Data at $N \ge 162$ are from the present work. Upper Q_{α} limits for ²⁶⁷Db and ²⁶⁸Db were calculated assuming hindrance factor of 3 (circles with arrows).

For the measured α -decay energies of the newly-produced isotopes, one can estimate half-lives for allowed transitions and compare them with experimental values under the Geiger-Nuttall treatment using the formula by Viola and Seaborg. Parameters are obtained from fits to the T_{α} vs. Q_{α} values of 65 known *even-even* nuclei with Z>82 and N>126. The ratios between experimental T_{exp} and calculated T_{calc} half-lives define the hindrance factors caused by odd numbers of protons and/or neutrons in the newly synthesized nuclei. The measured T_{exp} values closely reproduce the calculated ones for the first two nuclei of these chains; thus the element 115 and element 113 isotopes have rather low hindrance factors, if any, for α -decay. For the isotopes of elements 111, Mt and Bh, the difference between measured and calculated T_{α} values results in hindrance factors of 3-10. These match the hindrance factors that can be extracted for the deformed odd-odd nuclei ²⁷²111 and descendants produced in experiments at GSI [11] and RIKEN [12]. One can suppose that in this region of nuclei, a noticeable transition from spherical to deformed shapes occurs at Z=109-111, resulting in the complication of the level structures of these nuclei and in an increased probability of α -transitions going

through excited states. Another sign of such a shape transition might be the significant increase in the difference of α -decay energies of the neighboring isotopes observed as the decay chains reach Z=111, see Fig. 2. This assumption is in agreement with macroscopic-microscopic calculations [8]. The deformation parameter β_2 was calculated to be 0.072 and 0.138 for ²⁸⁸115 and ²⁸⁴113, respectively. As the decay chain recedes from the shell closure at Z=114, the deformation parameter β_2 increases to 0.200, 0.211 and 0.247 for ²⁸⁰111, ²⁷⁶Mt and ²⁷²Bh, respectively.

The α -decay energies of these synthesized isotopes are plotted in Fig. 2, in which the α -decay energies of known odd-Z isotopes with Z \ge 103 together with theoretical Q_{α} values [8] for nuclides with Z=103-115 are also shown. The α -decay energies of newly produced isotopes of Mt and Bh coincide well with theoretical values [8]. For the isotopes $^{279,280}111$ and $^{283,284}113$ the difference between theoretical and experimental Q_{α} values amount to 0.6-0.9 MeV. Some part of this deficient energy can be explained by possible γ -ray emission from excited levels populated during α -decay. Thus, low-lying level structure calculations for these nuclei are desirable for a more quantitative comparison with theory.

As a whole, the results of the present work demonstrate that in 48 Ca-induced reactions one can produce and study new nuclei over a wide range of Z and N. These investigations should result in significant new information on the influence of nuclear structure on the decay properties of superheavy nuclei.

Due to the hindrance to spontaneous fission caused by the odd proton, these odd-Z nuclei can undergo consecutive α -decays leading to the lighter transactinide elements that have a large neutron excess. The number of neutrons in such nuclides can be varied downward by using other target nuclei, e.g., ²⁴¹Am, ²³⁷Np or ²³¹Pa. Therefore, the investigation of the region of nuclei located near deformed shell closures Z=108 and N=162 that has been explored from the N<162 side in the cold fusion reactions [11,12] can be approached from the high-N side using ⁴⁸Ca-induced reactions. Note also that the rather long lifetimes of Db isotopes permit us to investigate, in more detail, the chemical properties of this element, previously studied only in on-line experiments with the short-lived isotopes ^{261,262,263}Db (T_{α} =1.8 s, 34 s and 27 s) (see, e.g., [16] and Refs. therein).

ACKNOWLEDGMENTS

We are grateful to the JINR Directorate, in particular to Profs. V.G. Kadyshevsky, Ts. Vylov and A.N. Sissakian for the help and support we received during all stages of the experiment. We would like to express our gratitude to the personnel of the U400 cyclotron and the associates of the ion-source group for obtaining an intense ⁴⁸Ca beam. This work has been performed with the support of the Russian Ministry of Atomic Energy and grants of RFBR No. 01-02-16486 and 03-02-06236. The ²⁴³Am target material was provided by RIAR, Dimitrovgrad, and by the U.S. DOE through ORNL. Much of the support for the LLNL authors was provided through the U.S. DOE under Contract No. W-7405-Eng-48. These studies were performed in the framework of the Russian Federation/U.S. Joint Coordinating Committee for Research on Fundamental Properties of Matter.

Оганесян Ю.Ц. и др. Эксперименты по синтезу 115 элемента в реакции ²⁴³Am (⁴⁸Ca, *xn*) ^{291-x}115

Представлены результаты эксперимента по синтезу изотопов 115 элемента в реакции ²⁴³ Am (⁴⁸Ca, *xn*) ^{291-*x*}115. При интегральной дозе пучка 4.3×10^{18} ионов ⁴⁸Ca с энергией 248 МэВ мы наблюдали три одинаковые цепочки распадов, состоящие из пяти последовательных α -распадов, зарегистрированных во временных интервалах около 20 с, и оканчивающиеся позднее спонтанным делением с большим выделением энергии (TKE~220 MэB). При более высокой энергии бомбардирующих частиц (253 МэВ) с такой же интегральной дозой была зарегистрирована другая цепочка из четырех последовательных α -распадов во временном интервале около 0.5 с, также оканчивающаяся спонтанным делением. Для девяти новых ядер были измерены энергии их α -распадов и времена жизни. Свойства распадов этих синтезированных ядер согласуются с последовательными α -распадами материнских изотопов нового 115 элемента - ²⁸⁸115 и ²⁸⁷115, полученных в каналах с испарением трех и четырех нейтронов с сечениями около 3 пб и 1 пб соответственно. Радиоактивные свойства новых нечетных по *Z* ядер (105-115) сравниваются с предсказаниями макро-микроскопической теории. Эксперименты были выполнены на циклотроне У-400 с использованием дубненского газонаполненного сепаратора ядер отдачи DGFRS (ЛЯР ОИЯИ).

Oganessian Yu.Ts. et al. Experiments on the synthesis of element 115 in the reaction 243 Am (48 Ca, *xn*) $^{291-x}$ 115

The results of experiments designed to synthesize element 115 isotopes in the ²⁴³Am(⁴⁸Ca, *xn*) ^{291-x}115 reaction are presented. With a beam dose of 4.3×10^{18} 248-MeV ⁴⁸Ca projectiles, we observed three similar decay chains consisting of five consecutive α -decays, all detected in time intervals of about 20 s and terminated at a later time by a spontaneous fission with a high energy release (TKE~220 MeV). At a higher bombarding energy of 253 MeV, with an equal ⁴⁸Ca beam dose, we registered a different decay chain of four consecutive α -decays detected in a time interval of about 0.5 s, also terminated by spontaneous fission. The α -decay energies and half-lives for nine new α -decaying nuclei were determined. The decay properties of these synthesized nuclei are consistent with consecutive α -decays originating from the parent isotopes of the new element 115, ²⁸⁸115 and ²⁸⁷115, produced in the 3*n*- and 4*n*-evaporation channels with cross sections of about 3 pb and 1 pb, respectively. The radioactive properties of the new odd-*Z* nuclei (105-115) are compared with the predictions of the macroscopic-microscopic theory. The experiments were carried out at the U400 cyclotron with the recoil separator DGFRS at FLNR, JINR.

The investigation has been performed at the Flerov Laboratory of Nuclear Reactions, JINR.

Oganessian Yu. Ts. et al. Experiments on the Synthesis of Element 115 in the Reaction 243 Am (48 Ca, xn) $^{291-x}$ 115

The results of experiments designed to synthesize element 115 isotopes in the ²⁴³Am (⁴⁸Ca, *xn*)^{291-*x*}115 reaction are presented. With a beam dose of $4.3 \cdot 10^{18}$ 248-Mev ⁴⁸Ca projectiles, we observed three similar decay chains consisting of five consecutive α -decays, all detected in time intervals of about 20 s and terminated at a later time by a spontaneous fission with a high energy release (TKE ~ 220 MeV). At a higher bombarding energy of 253 MeV, with an equal ⁴⁸Ca beam dose, we registered a different decay chain of four consecutive α -decays detected in a time interval of about 0.5 s, also terminated by spontaneous fission. The α -decay energies and half-lives for nine new α -decaying nuclei were determined. The decay properties of these synthesized nuclei are consistent with consecutive α -decays originating from the parent isotopes of the new element 115, ²⁸⁸115 and ²⁸⁷115, produced in the 3*n*- and 4*n*-evaporation channels with cross sections of about 3 and 1 pb, respectively. The radioactive properties of the new odd-*Z* nuclei (105–115) are compared with the predictions of the macroscopic-microscopic theory. The experiments were carried out at the U400 cyclotron with the recoil separator DGFRS (FLNR, JINR).

The investigation has been performed at the Flerov Laboratory of Nuclear Reactions, JINR.
