It is shown, for the self-consistent system of scalar, electro-magnetic and gravitational fields in general relativity, that the equations of motion admit a special kind of solutions with spherical or cylindrical symmetry. For these solutions, the physical fields vanish and the space-time is flat outside of the critical sphere or cylinder. Therefore, the mass and the electric charge of these configurations are zero. The principal difference between droplet-like solutions with spherical symmetry and those with cylindrical one has been established. In the first case there exists a possibility of continuous transformation of droplet-like configuration into the solitonian one, when for the second case there is no such a possibility.

I. INTRODUCTION

A specific type of solutions to the nonlinear field equations in flat space-time were obtained in a series of interesting articles [1], [2], [3], [4]. These solutions are known as droplet-like solutions or simply droplets. Distinguishable property of these solutions is the availability of some sharp boundary, defining the space domain, in which the material field happens to be located i.e. the field is zero beyond this area. As was found the solutions mentioned exist in field theory with specific interactions that can be considered as effective, generated by initial interactions of the unknown origin.

The aim of this paper is to consider self-consistent system to obtain droplet-like solutions in the framework of General Theory of Relativity. We show that in case of interacting electromagnetic and gravitation field system with specific type of interactions there exist droplet-like solutions having zero electric charge and mass. It is noteworthy to underline that the effective potentials, raised in this case, possess confining property i.e. create a strong repulsion in some configurational space.

We study the existence of regular static solutions, possessing spherical and/or cylindrical symmetry and sharp boundary, to the equations of scalar nonlinear electrodynamics in General Relativity. Excluding the scalar field we obtain the effective Lagrangian of nonlinear

* “Gravitation & Cosmology”, 4 (2(14)), pp. 114-120 (1998); IC/IR/96/10, 13 p.; gr-qc/9603032
electrodynamics. Contrary to the widely known soliton-like solutions, with field functions and energy density asymptotically tending to zero at spatial infinity, the solutions in question vanish at a finite distance from the center of the system (in the case of spherical symmetry) or from the axis (in the case of cylindrical symmetry). Thus, there exists the sphere or cylinder with critical radius \( r_0 \), outside of which the fields disappear. Therefore the field configurations have the droplet-like structure \[1\], \[5\], \[6\]. As is known, there do not exist regular static spherically or cylindrically symmetric configurations within the framework of gauge invariant nonlinear electrodynamics \[7\]. That is why we consider the generalized model, with the Lagrangian explicitly containing 4-potential \( A_\mu \), \( \mu = 0, 1, 2, 3 \), thus breaking the gauge invariance inside the critical sphere or cylinder. The corresponding terms appear due to the interaction between the electromagnetic and scalar fields. This interaction being negligible at large distances, the Maxwellian structure of the electromagnetic Lagrangian (and therefore the gauge invariance) is reinstated for \( r \gg r_0 \).

II. FUNDAMENTAL EQUATIONS

We choose the Lagrangian in the form \[7\]
\[
L = \mathcal{R}/2\kappa - (1/16\pi) \left[ \mathcal{F}_{\alpha\beta} \mathcal{F}^{\alpha\beta} + 2 \phi,\alpha \phi^{\alpha} \Psi(I) \right],
\]
where \( \kappa = 8\pi G \) is the Einstein’s gravitational constant and the function \( \Psi(I) \) of the invariant \( I = A_\mu A^\mu \) characterizes the interaction between the scalar \( \phi \) and electromagnetic \( A_\mu \) fields. In the sequel there will not appear any restrictions of the function \( \Psi(I) \), thus the Lagrangian (2.1) defines the class of models parameterized by \( \Psi(I) \).

The field equations corresponding to the Lagrangian (2.1) read
\[
\mathcal{G}^\nu_\mu = -\kappa T^\nu_\mu,
\]
\[
\partial_\alpha (\sqrt{-g} g^{\alpha\beta} \phi,\beta \Psi) = 0,
\]
\[
(1/\sqrt{-g}) \partial_\beta (\sqrt{-g} \mathcal{F}^{\alpha\beta}) + (\phi,\beta \phi^{\beta}) \Psi_I A^\alpha = 0,
\]
where \( \Psi_I = d\Psi/dI \) and \( \mathcal{G}^\nu_\mu = \mathcal{R}^\nu_\mu - \delta^\nu_\mu \mathcal{R}/2 \) is the Einstein tensor. One can write the energy-momentum tensor of the interacting matter fields in the form:
\[
T^\nu_\mu = (1/4\pi) \left[ \phi,\mu \phi^{\nu} \Psi(I) - \mathcal{F}_{\mu\alpha} \mathcal{F}^{\nu\alpha} + \phi,\alpha \phi^{\alpha} \Psi_I A_\mu A^\nu \right] +
\]
\[
+ \delta^\nu_\mu \left[ (1/16\pi) \left( \mathcal{F}_{\alpha\beta} \mathcal{F}^{\alpha\beta} + 2 \phi,\alpha \phi^{\alpha} \Psi(I) \right) \right].
\]

III. CONFIGURATIONS WITH SPHERICAL SYMMETRY

Searching for the static spherically-symmetric solutions to the system of equations (2.2) - (2.4), we consider the metric in the form \[8\]:
\[
ds^2 = e^{2\gamma} dt^2 - e^{2\alpha} d\xi^2 - e^{2\beta} [d\theta^2 + \sin^2 \theta \, d\phi^2].
\]
Let us now formulate the requirements to be fulfilled by particle-like solutions (PLS). These are \[9\]
(a) Stationarity [applied to the metric (3.1)] i.e.
\[ \alpha = \alpha(\xi), \quad \beta = \beta(\xi), \quad \gamma = \gamma(\xi); \]

(b) regularity of the metric and the matter fields in the whole space-time;
(c) asymptotically Schwarzschild metric and corresponding behavior of the field functions.

In view of requirement (a) it is convenient to choose the harmonic \( \xi \) coordinate (\( \Box \xi = 0 \)) in (3.1) to satisfy the subsidiary condition [10]:
\[ \alpha = 2 \beta + \gamma. \]  
(3.2)

The corresponding coordinate in flat space-time is just \( \xi = 1/r \).

With the constraint (3.2) the system of Einstein equations (2.2) reads:
\[ e^{-2\alpha} (2\beta'' - U) - e^{-2\beta} = -\kappa T_0^0, \]  
(3.3)
\[ e^{-2\alpha} U - e^{-2\beta} = -\kappa T_1^1, \]  
(3.4)
\[ e^{-2\alpha} (\beta'' + \gamma'' - U) = -\kappa T_2^2 = -\kappa \Omega_3^3, \]  
(3.5)

where \( U = \beta'' + 2\beta'\gamma' \), and \( \Omega \equiv d/d\xi \).

Note that the field functions, as well as the components of the metric tensor depend on the single spatial variable \( \xi \). Assuming the electromagnetic field to be determined by the time component \( A_0 = A(\xi) \) of the 4-potential one finds the unique non-trivial component of the field tensor \( F_{10} = A'_0 \), and the invariant \( I \) reduces to \( I = e^{-2\gamma} A^2(\xi) \).

One can write the non-zero components of the energy-momentum tensor (2.5) as follows:
\[ T_0^0 = (1/8\pi) e^{-2\alpha} [A^2 e^{-2\gamma} + \varphi^2 (\Psi - 2A^2 e^{-2\gamma} \Psi_I)], \]  
(3.6)
\[ T_1^1 = -T_2^2 = -T_3^3 = (1/8\pi) e^{-2\alpha} [A^2 e^{-2\gamma} - \varphi^2 \Psi]. \]  
(3.7)

Adding together the equations (3.4) and (3.5) and using the property \( T_1^1 + T_2^2 = 0 \), one obtains the differential equation
\[ \beta'' + \gamma'' - e^{2(\beta + \gamma)} = 0, \]
with the solution [11]
\[ e^{-(\beta + \gamma)} = S(k, \xi) = \begin{cases} 
  k^{-1} \sinh k\xi, & k > 0, \\
  \xi, & k = 0, \\
  k^{-1} \sin k\xi, & k < 0,
\end{cases} \]  
(3.8)

depending on the constant \( k \). Notice that another constant of integration is trivial, so that \( \xi = 0 \) corresponds to the spatial infinity, where \( e^\gamma = 1 \) and \( e^\beta = \infty \). Without loss of generality one can choose \( \xi > 0 \).

The scalar field equation (2.3) has the evident solution
\[ \varphi' = C P(I), \]  
(3.9)
where \( P(I) = 1/\Psi(I) \) and \( C \) is the integration constant. Putting (3.9) into (2.4) one gets the equation for the electromagnetic field
\[ (e^{-2\gamma} A')' - C^2 P_I e^{-2\gamma} A = 0, \]  
(3.10)
Yu.P. Rybakov, B. Saha and G.N. Shikin

where the second term could be naturally interpreted as the induced nonlinearity. In view of (3.9) one rewrites the Einstein equation (3.4) and the result of adding the equations (3.3) and (3.4) as follows:

\[ \gamma^2 = -G \left( C^2 P - A^2 e^{-2\gamma} \right) + K, \quad K = k^2 \text{sign} k, \]  
(3.11)

\[ \gamma'' = G e^{-2\gamma} \left( A^2 + C^2 A^2 P_I \right). \]  
(3.12)

One can easily check that the equation (3.11) is the first integral of the equations (3.10) and (3.12). Eliminating the term \((P_I A)\) between (3.10) and (3.12) one gets the equation:

\[ \gamma'' = G e^{-2\gamma} \left( A A' e^{-2\gamma} \right), \]  
(3.13)

with the evident first integral:

\[ \gamma' = G AA' e^{-2\gamma} + C_1, \quad C_1 = \text{const.} \]  
(3.14)

Let us consider the simple case \(C_1 = 0\). Then from (3.14) we get

\[ e^{2\gamma} = GA^2 + H, \quad H = \text{const.} \]  
(3.15)

Substituting \(\gamma'\) and \(e^{2\gamma}\) from (3.14) and (3.15) into (3.11), we find for \(A(\xi)\) the differential equation:

\[ A^2 (GA^2 + H)^{-2} = (GC^2 P - K) / GH, \]  
(3.16)

which can be solved by quadrature:

\[ \int \frac{dA}{(GA^2 + H) \sqrt{GC^2 P - K}} = \pm \left( \frac{1}{\sqrt{GH}} \right) (\xi - \xi_0), \quad \xi_0 = \text{const.} \]  
(3.17)

It is clear that the configuration obtained has a center if and only if \(e^\beta = 0\) at some \(\xi = \xi_c\).

One can show [10] that the conditions for the center \(\xi_c = \infty\) to be regular imply \(K = 0\) and the following behavior of the field quantities in the vicinity of the point \(\xi_c = \infty\):

\[ \gamma' = O(\xi^{-2}), \quad A' \to A_c \neq \infty, \quad A' \to 0, \]  
(3.18)

\[ \xi^4 P(I) \to 0, \quad |\xi^4 I P_I| < \infty. \]  
(3.19)

In view of (3.18) we deduce from (3.14) that \(C_1 = 0\) in accordance with the earlier supposition.

Now we can write the boundary conditions on the surface of the critical sphere \(\xi = \xi_0\):

\[ T^\nu_\mu = A = A' = 0, \quad e^\gamma = 1, \quad e^\beta = 1/\xi_0 > 0. \]  
(3.20)

Due to (3.20) and (3.15) we infer that \(H = 1\).

Let us now choose the function \(P(I)\) as follows [12]:

\[ P(I) = J^{(1 - 2/\sigma)} \left[ (1 - J)^{1/\sigma} - J^{1/\sigma} \right]^2 (1 - J), \]  
(3.21)
where \( J = G I; \quad \sigma = 2n + 1; \quad n = 1, 2, 3 \cdots \) Then on account of \( K = 0 \) and \( H = 1 \) we get from (3.17) the following expression for \( A(\xi) \):

\[
A(\xi) = (1/\sqrt{G}) \left[ 1 - \exp \left( -\frac{2C \sqrt{G}}{\sigma} (\xi - \xi_0) \right) \right]^{\sigma/2}.
\]

As one can see from (3.22), the conditions (3.18) and (3.19) for the center to be regular and the matching conditions (3.20) on the surface of the critical sphere are fulfilled if \( \sigma > 2 \). It is also obvious from (3.22) that for \( \xi < \xi_0 \) the value of square bracket turns to be negative one and \( A(\xi) \) becomes imaginary since \( \sigma \) is an odd number. Since we are interested in the real \( A(\xi) \) only, without loss of generality we may assume the value of \( A(\xi) \) be zero for \( \xi \leq \xi_0 \).

Recalling that \( J = G A^2 / (G A^2 + 1) \), we get from (3.22) that \( J(\infty) = 1/2 \) and \( J(\xi_0) = 0 \), thus implying:

\[
P(I) |_{\xi=\infty} = P(I) |_{\xi=\xi_0} = 0.
\]

It means that at \( \xi = \xi_c = \infty \) and \( \xi = \xi_0 \), the interaction function \( \Psi(I) = 1/P(I) \) is singular. It turns out nevertheless that the energy density \( T_0^0 \) is regular at these points due to the fact that it contains \( \Psi(I) \) as a multiplier in the form:

\[
e^{-2\alpha} \varphi^2 \Psi = C^2 e^{-2\alpha} P(I),
\]

which tends to zero as \( \xi \to \xi_c \) or \( \xi \to \xi_0 \).

As follows from (3.22), for the limiting case \( \xi_0 = 0 \), when the critical sphere goes to the spatial infinity and the solution in question is defined at \( 0 \leq \xi \leq \infty \), it appears that at spatial infinity \( (\xi = 0) \) \( A = 0 \) and \( P(I) = 0 \). In this case we obtain the usual soliton-like configuration not possessing any sharp boundary.

Note that at spatial infinity \( (\xi = 0) \) one can compare the metric found with the Schwarzschild one and the electrical field with the Coulomb one, thus determining the total mass \( m \) and the charge \( q \) of the system:

\[
G m = -\gamma'(0), \quad q = -A'(0).
\]

Taking into account that \( e^{2\gamma} = G A^2 + 1 \), one can find through the use of (3.22) that for \( \xi_0 = 0 \), \( A'(0) = -q = 0 \) and \( \gamma'(0) = -G m = 0 \). Therefore, the total energy of the soliton-like system, defined as the sum of the material fields energy and that of the gravitational field, vanishes. If now one chooses the integration constant \( \xi_0 > 0 \), then the field configuration with the sharp boundary (droplet) appears. In this case for \( \xi \leq \xi_0 \) one obtains \( A(\xi) = 0 \) and \( e^{2\gamma} = 1 \), i.e. outside of the droplet gravitational and electromagnetic fields disappear, that implies the vanishing of the total mass and the charge of the system. This unusual property makes the droplet-like object poorly visible for the outer observer.

Let us now calculate the matter field energy density:

\[
T_0^0 = (C^2 / 8\pi) e^{-2\alpha} \left[ P(I) + e^{2\gamma} + 2 IP(I) \right].
\]

To this end we substitute into (3.25) the expression for \( e^{-2\alpha} = \xi^4 (G A^2 + 1) \), \( P(I) \) and \( A(\xi) \) using (3.21) and (3.22). It should be emphasized that the field energy is localized in a small region \( (\xi_0 \leq \xi < \infty) \):

\[
T_0^0(\xi) |_{\xi=\infty} \to 0, \quad T_0^0(\xi) |_{\xi=\xi_0} \to 0,
\]

where
namely, inside the critical sphere with the radius

\[ R = \int_{0}^{\infty} d\xi e^{\alpha(\xi)} = \int_{0}^{\infty} d\xi /\xi^2 \left\{ \left[ 1 - e^{-2C\sqrt{G}(\xi-\xi_0)/\sigma} \right]^\sigma + 1 \right\}^{(1/2)} < \infty. \]

One can readily derive from (3.25) the energy \( E_f \) of the matter fields:

\[ E_f = \int d^3x \sqrt{-g} T_{00}^{\infty} = (C/2) \int_{0}^{1/\sqrt{G}} d\mathcal{A} e^{-3\gamma} \left[ \sqrt{P}(1 + e^{2\gamma}) + 4 I (\sqrt{P})_I \right], \quad (3.27) \]

Using (3.21) and the expressions

\[ e^{2\gamma} = 1/(1 - J), \quad \mathcal{A} = \sqrt{G P (1 - J)}, \]

one finds from (3.27) after integrating by parts,

\[ E_f = (C/4\sqrt{G}) \int_{0}^{1/2} [(2 - J)\sqrt{J P/(1 - J)} + 2 P_J \sqrt{J^3/P}] dJ = \]

\[ = (C/4\sqrt{G}) \int_{0}^{1/2} [(5 J - 4)\sqrt{J P/(1 - J)}] dJ < 0. \]

Knowing that the total energy of the droplet-like object is zero this inequality implies the positivity of its gravitational energy. Thus the droplet-like configuration of the fields obtained is totally regular with zero total energy (including the energy of proper gravitational field) and null electric charge and remains unobservable to one located outside the sphere with radius \( R \ [12], \ [13] \).

In order to clarify the fact that the role of the gravitational field in forming the droplet-like configuration is not decisive it is worthwhile to compare the solution obtained with that in the flat space-time, described by the interval

\[ ds^2 = dt^2 - dr^2 - r^2 [d\theta^2 + \sin^2\theta d\phi^2]. \]

In the latter case the equation (2.3) admits the solution

\[ \varphi'(r) = C P(r)/r^2. \quad (3.28) \]

Substituting (3.28) into (2.4), one finds that the equation for the electromagnetic field can be solved by quadrature:

\[ \int d\mathcal{A}/\sqrt{P} = \pm C \left( \frac{1}{r} - \frac{1}{r_0} \right), \quad r_0 = \text{const.} \quad (3.29) \]

Note that the droplet-like configuration \( \mathcal{A}(r) \) will be similar to (3.22) if one chooses the function \( P(I) \) more simple than (3.21):

\[ P(I) = J^{1-2/\sigma} (1 - J^{1/\sigma})^2, \quad J = \lambda I, \quad (3.30) \]
where \( \lambda = \text{const}; \ \sigma = 2n + 1; \ \ n = 1, 2, 3, \cdots \). Then substituting (3.30) into (3.29) one gets the solution

\[
\mathcal{A}(r) = \left(1/\sqrt{\lambda}\right) [1 - \exp\left(-\frac{2C\lambda}{\sigma} \left(\frac{1}{r} - \frac{1}{r_0}\right)\right)]^{\sigma/2}.
\]  

(3.31)

One can see from (3.31) that \( \mathcal{A}(r) = 0 \) as \( r \geq r_0 \), i.e. the charge of the flat space-time droplet configuration also vanishes. For this solution the regularity conditions at the center \( r = 0 \) and on the surface of the critical sphere \( r = r_0 \) are evidently fulfilled. It similarly appears that for \( r = \infty \) one finds the usual soliton-like structure with field vanishing as \( r \to \infty \). The field energy \( E_f \) is defined as follows:

\[
E_f = C \int_{\mathcal{A}(r_0)}^{\mathcal{A}(0)} dA \left(\sqrt{P} + I P I / \sqrt{P}\right) = C \sqrt{P I} \left[\mathcal{A}(0) / \mathcal{A}(r_0)\right].
\]  

(3.32)

Inspecting that \( PI = 0 \) both at \( r = 0 \) and \( r = r_0 \), we arrive through (3.32) at \( E_f = 0 \).

Thus in the flat space-time as well as for the self-gravitating system, the total energy and charge of the droplet-like configuration vanish.

IV. CONFIGURATIONS WITH CYLINDRICAL SYMMETRY

Let us now search for static cylindrically-symmetric solutions to the equations (2.2)-(2.4). In this case the metric can be chosen as follows [14], [15]:

\[
ds^2 = e^{2\gamma} dt^2 - e^{2\alpha} dx^2 - e^{2\beta} d\phi^2 - e^{2\mu} dz^2.
\]  

(4.1)

FIG. 1: View of droplet-like solution. For convenient here we use the following notations: \( \frac{2\lambda}{\sigma r} := \frac{1}{x} \) and \( \frac{2\lambda}{\sigma r_0} := \frac{1}{x_0} \). The configurations are plotted for \( \lambda = 1, \ x_0 = 2 \) and \( \sigma \) takes the values 3, 5, 7, 9.
FIG. 2: view of the inverse function to the interaction one (i.e. $P(I)$) that provides us with the droplet-like configurations (Fig. 1). As is seen from Fig. 1, the stronger the interaction the more localized the corresponding droplet-like configuration.

The requirements to be fulfilled by soliton-like solutions (PLS) in this case are [16]
(a) Stationarity [applied to the metric (4.1)] i.e.

$$\alpha = \alpha(x), \quad \beta = \beta(x), \quad \gamma = \gamma(x), \quad \mu = \mu(x);$$

It means in (4.1) all the components of the metrical tensor depend on the single spatial coordinate $x \in [x_0, x_a]$, where $x_a$ is the value of $x$ on the axis of symmetry, defined by the condition $\exp[\beta(x_a)] = 0$, and $x_0$ is the value of $x$ on the surface of the critical cylinder. The coordinates $z$ and $\phi$ take their standard values: $z \in [-\infty, \infty], \quad \phi \in [0, 2\pi]$.

(b) regularity of the metric and the matter fields in the whole space-time;
(c) localized in space-time (with limited field energy):

$$E_f = \int T_0^0 \sqrt{-g} \, dV < \infty.$$

Requirement (c) assumes the rapid decreasing of energy density of material field at spatial infinity, which together with (b) guaranties the finiteness of $E_f$. Let us note that $E_f$ may be finite even for singular solutions on the axis. Requirement (b) means the regularity of material fields as well as the regularity of metric functions that entails the demand of finiteness of energy-momentum tensor of material fields all over the space.

In view of requirement (a) it is convenient to choose the coordinate $x$ in (4.1) to satisfy the subsidiary condition [15]:

$$\alpha = \beta + \gamma + \mu,$$

that permits to present the system of the Einstein equations in the form:

$$\mu'' + \beta'' - V = -\kappa T_0^0 e^{2\alpha}, \quad (4.2)$$
\[ \mu' \beta' + \beta' \gamma' + \gamma' \mu' = V = -\kappa T^1_1 e^{2\alpha}, \quad (4.3) \]
\[ \gamma'' + \beta'' - V = -\kappa T^2_2 e^{2\alpha}, \quad (4.4) \]
\[ \mu'' + \gamma'' - V = -\kappa T^3_3 e^{2\alpha}, \quad (4.5) \]

As in the preceding section, the electromagnetic field is described by the time component of the 4-potential \( A_0(x) = A(x) \) and by the component \( F_{10} = dA/dx = A' \) of the field strength tensor and the energy-momentum tensor of interacting fields is defined by the equations (3.6), (3.7).

Adding together the equations (4.3) and (4.4) and using (3.7), one obtains the simple equation:
\[ \gamma'' + \beta'' = 0, \quad (4.6) \]
with the solution
\[ \beta(x) + \gamma(x) = C_2 x, \quad C_2 = \text{const.} \quad (4.7) \]
Notice that the second integration constant in (4.7) can be taken trivial, as it determines only the choice of scale.

In a similar way the addition of equations (4.3) and (4.5) leads to the equation:
\[ \gamma'' + \mu'' = 0, \quad (4.8) \]
with the solution
\[ \mu(x) + \gamma(x) = C_3 x, \quad C_3 = \text{const.} \quad (4.9) \]
Solving the equation (2.2) in the metric (4.1), one gets the same result as in (3.9), i.e.
\[ \varphi'(x) = C P(I). \quad (4.10) \]
Substituting (4.10) into (2.4), one finds the equation for the electromagnetic field, coincident with (3.10).

Now as in the previous case, we use the equation (4.3) and sum of equations (4.2) and (4.3) which in view of (4.6) and (4.8), take the form:
\[ \gamma^2 - C_2 C_3 = -G \left( C^2 P - A^2 e^{-2\gamma} \right), \quad (4.11) \]
\[ \gamma'' = G e^{-2\gamma} \left( A'^2 + C^2 A^2 P_I \right). \quad (4.12) \]
Elimination of \( P_I A \) between the equations (3.10) and (4.12) gives the equation (3.13) with the solution (3.14). Integrating (3.14) under the choice \( C_1 = 0 \), one obtains the equality (3.15). Finally, substituting \( \gamma' \) from (3.14) and \( e^{2\gamma} \) from (3.15) into (4.11), one gets the equation for \( A(x) \):
\[ A^2 (G A^2 + H)^{-2} = (G C^2 P - C_2 C_3) / G H. \quad (4.13) \]
The equation (4.13) can be solved by quadrature:
\[ \int \frac{dA}{(G A^2 + H) \sqrt{G C^2 P - C_2 C_3}} = \pm \left( \frac{1}{\sqrt{G H}} \right) (x - x_0). \quad (4.14) \]
Let us formulate regularity conditions to be satisfied by the solutions to the equations (2.2)-(2.4) on the axis of symmetry defined by the value \( x = x_a \), where \( \beta(x_a) = -\infty \). Choosing in (4.7) \( C_2 < 0 \) and taking into account that for the regular solutions \( |\gamma| < \infty \), we get \( x_a = \infty \). The regularity conditions are similar to (3.18) and (3.19) for the case of spherical symmetry, implying that the following relations hold as \( x \to x_a = \infty \):

\[
\begin{align*}
\gamma' & \to 0, \quad \mathcal{A}' \to \mathcal{A}, \quad \mathcal{A}' \to 0, \quad (4.15) \\
 e^{2C_2|x|} P(I) & \to 0, \quad e^{2C_2|x|} |I P_I| < \infty, \quad C_3 \neq 0. \quad (4.16)
\end{align*}
\]

Boundary conditions on the surface of the critical cylinder \( x = x_a \) can be written as follows:

\[
T_{\mu} = \mathcal{A} = \mathcal{A}' = 0, \quad e^\gamma = 1, \quad e^\beta = e^{-|C_2|x} > 0. \quad (4.17)
\]

The conditions (4.17) together with the relations \( e^{2\gamma} = G \mathcal{A}^2 + H \), imply that \( H = 1 \).

Choosing \( P(I) \) in the form (3.21), one can find the expression for \( \mathcal{A}(x) \) which is similar to (3.22):

\[
\mathcal{A}(x) = (1/\sqrt{G}) \left[ 1 - \exp \left( -\frac{2C}{\sqrt{G}} \left( x - x_0 \right) \right) \right]^{\alpha/2}. \quad (4.18)
\]

As one can readily see from (4.18), the conditions (4.15), (4.16) and (4.17) are fulfilled if \( |C_2| \leq C_\sqrt{G}/\sigma \). It is noteworthy that at \( x \leq x_0 \), \( \mathcal{A}(x) \equiv 0 \) and the space-time is flat, the gravitational field being absent [17].

There is a principal difference between solutions (3.22) and (4.18). For the case of spherical symmetry the droplet-like solution can be transformed to the soliton-like one if the boundary \( x_0 \) is removed by putting \( \xi_0 = 0 \) (as in this case \( \exp(\beta(\xi_0)) = 1/\xi_0 = \infty \)). On the contrary, for the case of cylindrical symmetry the removal of the boundary is equivalent to putting \( x_0 = -\infty \), as in this case \( \exp(\beta(x_0)) = \exp(- |C_2| x_0) = \infty \). Under this last choice the solution (4.18) takes constant value \( \mathcal{A}(x) = 1/\sqrt{G} \) and the soliton structure disappears. For the considered case, as well as for that of spherical symmetry, the density of the field energy is given by equation (3.25) and the linear density of energy is similar to (3.27):

\[
E_f = (C/4) \int_0^{1/\sqrt{G}} d\mathcal{A} e^{-3\gamma} \left[ \sqrt{P}(1 + e^{2\gamma}) + 4 I (\sqrt{P})_I \right], \quad (4.19)
\]

Substituting \( P(I) \) from (3.21) into (4.19), one can find that \( E_f \) is finite and the total energy \( E_f + E_p \) turns out to be zero.

Let us now define the effective charge density \( \rho_e \) and total charge \( Q \), corresponding to the unit length on z-axis. In generally from (2.4) one gets [16]

\[
\rho_e = \frac{1}{4\pi} \left( \varphi, \beta \varphi, \beta \right) \Psi_I \mathcal{A}, \quad (4.20)
\]

that for static radial electric field leads to

\[
\rho_e = \frac{C^2}{4\pi} e^{-2(\alpha+\gamma)} P_I \mathcal{A}. \quad (4.21)
\]

Then for chronometric invariant electric charge density \( \rho_e \) we have

\[
\rho_e = \frac{\rho_e}{\sqrt{g^{00}}} = \frac{C^2}{4\pi} e^{-(2\alpha+\gamma)} P_I \mathcal{A}. \quad (4.22)
\]
The total charge is defined from the equality
\[ Q = 2\pi \int_{x_a}^{x_\infty} \rho \sqrt{-3g} \, dx. \]  
(4.23)

Putting the corresponding quantities into the foregoing equality after some simple calculations we obtain
\[ Q = \frac{1}{2} e^{-2\gamma} A' |_{x_\infty}^{x_a} = 0. \]  
(4.24)

Now it is worthwhile to make again the comparison with the flat-space solutions of the equations (2.3) and (2.4), using the interval:
\[ ds^2 = dt^2 - d\rho^2 - \rho^2 d\phi^2 - dz^2. \]

In this case the scalar field equation (2.3) admits the solution:
\[ \varphi' (\rho) = C P(I) / \rho, \quad P(I) = 1/\Psi(I), \quad C = \text{const}. \]  
(4.25)

Inserting (4.25) into (2.4), one can find the electromagnetic field equation which admits the solution in quadratures:
\[ \int \frac{dA}{\sqrt{P(I)}} = \pm C \ln \frac{\rho}{\rho_0}, \quad \rho_0 = \text{const}. \]  
(4.26)

Substituting \( P(I) \) from (3.30) in (4.26), one gets the solution of the droplet-like form:
\[ A(\rho) = (1/\sqrt{\lambda}) \left[ 1 - \left( \frac{\rho}{\rho_0} \right)^2 \lambda^{\sqrt{\lambda}/\sigma} \right]^{\sigma/2}. \]  
(4.27)

One concludes from (4.27) that \( A(\rho \geq \rho_0) \equiv 0 \). It means that the electric charge of the system is zero. For the solution (4.27) the regularity conditions both on the axis \( \rho = 0 \) and on the surface of the critical cylinder \( \rho = \rho_0 \) are fulfilled if \( C \lambda^{\sqrt{\lambda} / \sigma} \). It is noteworthy that in the case of cylindrical symmetry, both in the flat space-time and with account of the proper gravitational field, there do not exist any soliton-like solutions, as for the choice \( \rho_0 = \infty \) the solution (4.27) degenerates into the constant: \( A(\rho) = 1/\sqrt{\lambda} \).

The linear density of the field energy in flat space-time can be found from the expression similar to (3.32), and as well as in the case of spherical symmetry, it is equal to zero:
\[ E_f = \frac{C'}{2} \sqrt{P I} |_{A(\rho_0)}^{A(0)} = 0, \]
as was expected.

V. DISCUSSION

Before summing up the results we need to say two words about the interaction Lagrangian. In 1951 J. Schwinger [18] applied the method to compute the effective coupling between a zero spin neutral meson and the electromagnetic field. To write the interaction between
scalar and electromagnetic fields we use some arbitrary functions of electromagnetic field. Thus our approach to generate an effective Lagrangian generalizes the one proposed by Schwinger. The particular choice of $P(I)$ was made to obtain droplet-like configurations. Using $P(I)$ that differs from (3.21) one can obtain quite different a solution (see e.g. [16]). Let us now sum up the results obtained.

Exact regular statically spherical- and cylindrical-symmetrical solutions with sharp boundary (droplet-like solutions) to the equations of scalar nonlinear electrodynamics in General Relativity have been obtained. It is shown that outside the droplet gravitational and electromagnetic fields remain absent i.e. total energy and total charge of the configuration are zero. We underline once more the principal difference between the droplet-like solutions with spherical symmetry and those with cylindrical one. In the first case there exists a possibility of continuous transformation of the droplet-like configuration into the solitonian one by transporting the sharp boundary to the infinity. As for the second case, there is no such a possibility, and the soliton-like configuration disappears when the boundary is smoothed tending to the infinity. Further we intend to study the interaction processes of droplets with external electromagnetic and gravitational fields and also the scattering of photons and electrons on droplets.
